**Aromatic oxyphenyl and Aromatic sulfanyphenyl derivatives**

5 The present invention relates to novel compounds which are glycine transporter inhibitors and as such effective in the treatment of disorders in the CNS, such as schizophrenia.

**Background of the invention**

10 Glutamic acid is the major excitatory amino acid in the mammalian central nervous system (CNS), and acts through two classes of receptors, the ionotropic and metabotropic receptors, respectively. The ionotropic glutamate receptors are divided into three subtypes based on the affinities of agonists for these receptors, namely *N*-methyl-D-aspartate (NMDA), (*R,S*)-2-amino-3-(3-hydroxy-5-methylisoxazol-4-yl)propanoic acid (AMPA) and kainic acid (or kainate) receptors.

15 The NMDA receptor contains binding sites for modulatory compounds such as glycine and polyamines. Binding of glycine to its receptor enhances the NMDA receptor activation. Such NMDA receptor activation may be beneficial for the treatment of schizophrenia and other diseases linked to NMDA receptor dysfunction. An activation can be achieved by an inhibitor of the glycine transporter.

20 Molecular cloning has revealed the existence of two types of glycine transporters, GlyT-1 and GlyT-2, wherein GlyT-1 can be further subdivided into GlyT-1a, GlyT-1b and GlyT-1c.

25 The NMDA receptor is blocked by compounds such as phencyclidine which induce a psychotic state which resembles schizophrenia. Likewise, the NMDA antagonists, such as ketamine, induce negative and cognitive symptoms similar to schizophrenia. This indicates that NMDA receptor dysfunction is involved in the pathophysiology of schizophrenia.

30 The NMDA receptor has been associated with a number of diseases, such as pain (Yaksh *Pain* 1989, 37, 111-123), spasticity, myoclonus and epilepsy (Truong et. al. *Movement Disorders* 1988, 3, 77-87), learning and memory (Rison et. al. *Neurosci.*

*Biobehav. Rev.* 1995, 19, 533-552), post-traumatic stress disorder (abbreviated: PTSD) (Heresco-levy et. al. *The International Journal of Neuropsychopharmacology*, 2002, 5:301-307, entitled: "Pilot-controlled trial of D-cycloserine for the treatment of post-traumatic stress disorder").

5

Glycine transporter antagonists or inhibitors are believed to be highly beneficial in the treatment of schizophrenia (Javitt WO 97/20533).

10 Glycine transport antagonists or inhibitors could be useful for the treatment of both the positive and the negative symptoms of schizophrenia and other psychoses, and in the improvement of cognition in conditions where the cognitive processes are diminished, i.e. Alzheimer's disease, multi-infarct dementia, AIDS dementia, Huntington's disease, Parkinson's disease, amyotrophic lateral sclerosis or diseases wherein the brain is damaged by inner or outer influence, such as trauma to the head  
15 or stroke. Likewise, convulsive disorders such as epilepsy, spasticity or myoclonus may benefit from glycine transporter antagonists.

Clinical trials with glycine have been reported, Javitt et. al. *Am. J. Psychiatry* 1994, 151, 1234-1236 and Leiderman et. al. *Biol. Psychiatry* 1996, 39, 213-215. The  
20 treatment with high-dose glycine is reported to improve the symptoms of schizophrenia. There is a need for more efficient compounds for the treatment of NMDA associated diseases.

The compounds of the present invention may also be resolved by the formation of  
5 diastereomeric derivatives.

Additional methods for the resolution of optical isomers, known to those skilled in the art, may be used. Such methods include those discussed by J. Jaques, A. Collet and S. Wilen in "Enantiomers, Racemates, and Resolutions", John Wiley and Sons, New  
10 York (1981).

20

(II)

with a phenol of formula III

(III)

wherein  $R^1, R^2, R^3, R^4, R^5, R^6, R^7, R^8, R^9, R^{9'}, R^{10}, X$  and  $Y$  are as defined in formula I above.

The reaction is typically performed in a suitable solvent such as tetrahydrofuran or diethyl ether containing a coupling agent such as triphenylphosphine and diethylazodicarboxylate or 1,1'-(Azodicarbonyl)dipiperidine at room temperature.

Alternatively, the present invention relates to a method of preparing a compound of formula I, comprising alkylation of an amine of formula IV

(IV)

with an alkylating agent of formula V

(V)

wherein  $R^1, R^2, R^3, R^4, R^5, R^6, R^7, R^8, R^9, R^{9'}, R^{10}, X$  and  $Y$  are as defined in formula I above, and  $L$  is a suitable leaving group such as halogen, mesylate or tosylate.

The reaction is typically performed in a suitable solvent such as ethanol, N,N-dimethylformamide or acetonitrile containing an inorganic base such as potassium or cesium carbonate or an organic base such N-ethyl diisopropylamine at an elevated temperature of 40-80 °C.

Alternatively compounds of formula I may be prepared by coupling intermediates of formula VI where  $Z$  is an iodide,  $R^1-R^{10}$  are as described above and  $Y$  is sulfur.

(VI)

with intermediates of formula VII

(VII)

The cross coupling reaction is typically performed as described by Schopfer (Tetrahedron, **2001**, 57, 3069-3073) where an iodide of formula IV is coupled to a thiol of formula  $R^5-S-H$  using palladium catalysis in toluene at elevated temperatures.

Compounds of formula I wherein  $R^{10}$  is hydrogen may be prepared by hydrolysis of the corresponding esters  $COOR^{10}$  wherein  $R^{10}$  is an insoluble polymer or e.g.  $C_{1-6}$ -alkyl, aryl or aryl- $C_{1-6}$ -alkyl. This may be performed under basic conditions, for example, using aqueous sodium hydroxide in an alcoholic solvent or under acidic conditions in the hydrolysis of a tertiary-butyl ester or cleavage from an insoluble polymer. This, method is also an aspect of the present invention.

### Pharmaceutical compositions

The compounds of the invention may be administered alone or in combination with pharmaceutically acceptable carriers or excipients, in either single or multiple doses. The pharmaceutical compositions according to the invention may be formulated with pharmaceutically acceptable carriers or diluents as well as any other known adjuvants and excipients in accordance with conventional techniques such as those disclosed in Remington: The Science and Practice of Pharmacy, 19 Edition, Gennaro, Ed., Mack Publishing Co., Easton, PA, 1995.

The pharmaceutical compositions may be specifically formulated for administration by any suitable route such as the oral, rectal, nasal, pulmonary, topical (including buccal and sublingual), transdermal, intracisternal, intraperitoneal, vaginal and parenteral (including subcutaneous, intramuscular, intrathecal, intravenous and intradermal) route, the oral route being preferred. It will be appreciated that the preferred route will depend on the general condition and age of the subject to be treated, the nature of the condition to be treated and the active ingredient chosen.

Pharmaceutical compositions for oral administration include solid dosage forms such as capsules, tablets, dragees, pills, lozenges, powders and granules. Where appropriate, they can be prepared with coatings such as enteric coatings or they can be formulated so as to provide controlled release of the active ingredient such as sustained or prolonged release according to methods well known in the art.

Liquid dosage forms for oral administration include solutions, emulsions, suspensions, syrups and elixirs.

Pharmaceutical compositions for parenteral administration include sterile aqueous and nonaqueous injectable solutions, dispersions, suspensions or emulsions as well as sterile powders to be reconstituted in sterile injectable solutions or dispersions prior to use. Depot injectable formulations are also contemplated as being within the scope of the present invention.

Other suitable administration forms include suppositories, sprays, ointments, cremes, gels, inhalants, dermal patches, implants, etc.

A typical oral dosage is in the range of from about 0.001 to about 100 mg/kg body weight per day, preferably from about 0.01 to about 50 mg/kg body weight per day, and more preferred from about 0.05 to about 10 mg/kg body weight per day administered in one or more dosages such as 1 to 3 dosages. The exact dosage will depend upon the frequency and mode of administration, the sex, age, weight and general condition of the subject treated, the nature and severity of the condition treated and any concomitant diseases to be treated and other factors evident to those

skilled in the art.

The formulations may conveniently be presented in unit dosage form by methods known to those skilled in the art. A typical unit dosage form for oral administration  
5 one or more times per day such as 1 to 3 times per day may contain from 0.01 to about 1000 mg, preferably from about 0.05 to about 500 mg, and more preferred from about 0.5 mg to about 200 mg.

For parenteral routes such as intravenous, intrathecal, intramuscular and similar  
10 administration, typically doses are in the order of about half the dose employed for oral administration.

The compounds of this invention are generally utilized as the free substance or as a pharmaceutically acceptable salt thereof. One example is a base addition salt of a  
15 compound having the utility of a free acid. When a compound of the formula (I) contains a free acid such salts are prepared in a conventional manner by treating a solution or suspension of a free acid of the formula (I) with a chemical equivalent of a pharmaceutically acceptable base. Representative examples are mentioned above.

20 For parenteral administration, solutions of the novel compounds of the formula (I) in sterile aqueous solution, aqueous propylene glycol, aqueous vitamin E or sesame or peanut oil may be employed. Such aqueous solutions should be suitably buffered if necessary and the liquid diluent first rendered isotonic with sufficient saline or glucose. The aqueous solutions are particularly suitable for intravenous,  
25 intramuscular, subcutaneous and intraperitoneal administration. The sterile aqueous media employed are all readily available by standard techniques known to those skilled in the art.

Suitable pharmaceutical carriers include inert solid diluents or fillers, sterile aqueous  
30 solution and various organic solvents. Examples of solid carriers are lactose, terra alba, sucrose, cyclodextrin, talc, gelatine, agar, pectin, acacia, magnesium stearate, stearic acid and lower alkyl ethers of cellulose. Examples of liquid carriers are syrup, peanut oil, olive oil, phospho lipids, fatty acids, fatty acid amines, polyoxyethylene

and water. Similarly, the carrier or diluent may include any sustained release material known in the art, such as glyceryl monostearate or glyceryl distearate, alone or mixed with a wax. The pharmaceutical compositions formed by combining the novel compounds of the formula (I) and the pharmaceutical acceptable carriers are then readily administered in a variety of dosage forms suitable for the disclosed routes of administration. The formulations may conveniently be presented in unit dosage form by methods known in the art of pharmacy.

Formulations of the present invention suitable for oral administration may be presented as discrete units such as capsules or tablets, each containing a predetermined amount of the active ingredient, and which may include a suitable excipient. Furthermore, the orally available formulations may be in the form of a powder or granules, a solution or suspension in an aqueous or non-aqueous liquid, or an oil-in-water or water-in-oil liquid emulsion.

If a solid carrier is used for oral administration, the preparation may be a tablet, placed in a hard gelatin capsule in powder or pellet form or it can be in the form of a troche or lozenge.

The amount of solid carrier will vary widely but will usually be from about 25 mg to about 1 g.

If a liquid carrier is used, the preparation may be in the form of a syrup, emulsion, soft gelatin capsule or sterile injectable liquid such as an aqueous or non-aqueous liquid suspension or solution.

#### **Method of preparing the compounds of formula I**

The compounds of the invention are prepared by the following general methods.

Coupling of alcohol of formula II with a phenol of formula III

(II)

(III)

The substituents  $R^1$ - $R^{10}$  are as defined above, X is oxygen and Y is oxygen or sulfur. The reaction is typically performed in a suitable solvent such as tetrahydrofuran or diethyl ether containing a coupling agent such as a combination of a triaryl phosphine and diethylazodicarboxylate or 1,1'-(Azodicarbonyl)dipiperidine at room temperature as described by Mitsunobu (Synthesis, 1981,1)

Alternatively compounds of the invention may be prepared by alkylation of amines of formula IV with alkylating agents of formula V.

(IV)

(V)

The substituents  $R^1$ - $R^{10}$ , X and Y are as defined above. L is a suitable leaving group such as halogen, mesylate or tosylate. The reaction is typically performed in a suitable solvent such as ethanol, N,N- dimethylformamide or acetonitrile containing an inorganic base such as potassium or cesium carbonate or an organic base such N-ethyl diisopropylamine at an elevated temperature of 40-80 °C.

Alternatively, compounds of the invention may be prepared by coupling intermediates of formula VI where Z is an iodide,  $R^1$ - $R^{10}$  are as described above and Y is sulfur.

(VI)

(VII)

The cross coupling reaction is typically performed as described by Schopfer (Tetrahedron, 2001, 57, 3069-3073) where an iodide of formula IV is coupled to a thiol of formula  $R^5-S-H$  using palladium catalysis in toluene at elevated temperatures.

5

Compounds of formula I wherein  $R^{10}$  is hydrogen may be prepared by hydrolysis of the corresponding esters  $COOR^{10}$  wherein  $R^{10}$  is an insoluble polymer or  $C_{1-6}$ -alkyl, aryl or aryl- $C_{1-6}$ -alkyl. This may be performed under basic conditions, for example, using aqueous sodium hydroxide in an alcoholic solvent or under acidic conditions in the hydrolysis of a tertiary-butyl ester or cleavage from an insoluble polymer.

10

Compounds of formula II may be prepared as depicted in scheme 1.

15

## Scheme 1

An amino acid derivative of formula VIII where  $R^{10}$ ,  $R^9$ ,  $R^9$  and  $R^8$  are as defined above may be alkylated with an alkylating reagent of formula IX. Alternatively an acetic acid derivative of formula X where  $R^{10}$ ,  $R^9$ ,  $R^9$  are as defined above and L is a halogen, mesylate or tosylate may be reacted with an amine of formula XI where  $R^5$ ,  $R^6$  and  $R^7$  are defined as above. The reaction is typically performed in a suitable solvent such as ethanol, N,N- dimethylformamide, DMSO or acetonitrile containing an inorganic base such as potassium or cesium carbonate or an organic base such N-ethyl diisopropylamine at an elevated temperature of 40-150 °C. P may be hydrogen or a suitable protecting group for an alcohol known to those skilled in the art. This could for example be tert-butyl dimethyl silyl or tetrahydropyranyl. The methods for the protection and deprotection of alcohols are described in the textbook *Protective Groups in Organic Synthesis*, T.W.Greene and p.G.M. Wuts, Wiley Interscience, (1991) ISBN 0571623016

Intermediates of formula III were prepared from 2-cyclohexanone as described by Samoshin et al. (*Tet. Lett.* **1994**, *35*, 7413-7414). Alternatively an appropriately substituted 2-halo-anisole may be metallated with an alkaline metal such as magnesium (Gilman, *Recl. Trav. Chim. Pays-Bas* **1935**, 588) or lithium (Hader et al, *J.Organomet.Chem.* **1989**, *364*, 1-16) and reacted with bis aryl bissulfides. Alternatively 2-halo-anisoles in the case of the halogen being iodide may be coupled using palladium/phosphine catalysis with a thiophenol as described in the general method of Schopfer (*Tetrahedron* **2001**, *57*, 3069-3073) to give intermediates, after demethylation of the anisole, of formula III.

Intermediates of formula IV are typically commercially available or their syntheses are well described in the literature.

Compounds of formula V where X is O may be prepared by reacting intermediates of formula III with trimethylene carbonate to give the O-hydroxyethyl derivative which can then be converted to compounds of formula V. Where L is Cl this could be using carbon tetrachloride and triphenylphosphine in dichloromethane. In the case of tosylate and mesylate this could be by the use of tosyl chloride or methane sulfonyl

chloride respectively in a solvent such as dichloromethane or tetrahydrofuran. These methods are standard to those skilled in the art. Compounds of formula V where X is carbon may be prepared by the alkylation of suitably substituted 2-iodo-benzylhalides with diethyl malonate in the general procedure described by L.F. Fieser, E. Berliner,  
 5 *J. Am. Chem. Soc.* **1952**, *74*, 536 to give 2-iodo-phenylpropionic acids. In the case of X is sulfur, coupling with an appropriate thiophenol using copper catalysis according to the method of Bartl et al, *Collection Czechoslovak Chem. Commun.* **1981**, *46*, 141 affords the 2-(arylsulfanyl)phenyl propionic acid which can be reduced using standard methods such as borane-tetrahydrofuran complex or lithium aluminium hydride to 2-  
 10 (arylsulfanyl)phenyl propanol. Activation of the alcohol to nucleophilic displacement can be performed as described above.

Compounds of formula VI may be prepared by the reaction of intermediates of formula II with intermediates of formula XII. The substituents  $R^1$ - $R^{10}$  are as defined  
 15 above, X is oxygen, sulphur or  $CR^{11}R^{12}$ , wherein  $R^{11}$  and  $R^{12}$  are as defined above, and Z is an iodide. The reaction is typically performed in a suitable solvent such as tetrahydrofuran or diethyl ether containing a coupling agent such as triphenyl phosphine and diethylazodicarboxylate or 1,1'-(Azodicarbonyl)dipiperidine at room temperature.

20

Intermediates of formula XII where Z is an iodide are commercially available or can  
 25 be easily obtained by demethylation of the corresponding 2-iodo-anisole using for example boron tribromide in toluene or similar methods well known to those skilled in the art. Alternatively treatment of the corresponding anisole with tert-butyl lithium and quenching with iodine as described by Iwao (*J. Org. Chem.* **1990**, *55*, 3622-3627)

and subsequent demethylation will also provide intermediates of formula XII. A third approach is the conversion of the appropriate 2-methoxy aniline derivative to the iodide in a Sandmeyer reaction as described by Still (*J. Org. Chem.* 1987, 52, 748-753), followed by demethylation to give intermediates of formula XII. These methods are all well described in the literature.

### Pharmacological testing

The compounds of the invention were tested in a well-recognised and reliable test measuring glycine uptake:

#### [<sup>3</sup>H]-Glycine uptake

Cells transfected with the human GlyT-1b were seeded in 96 well plates. Prior to the experiment the cells were washed twice in HBS (10 mM Hepes-tris (pH 7.4), 2.5 mM KCl, 1 mM CaCl<sub>2</sub>, 2.5 mM MgSO<sub>4</sub>) and pre-incubated with test compound for 6 minutes. Afterwards, 10 nM [<sup>3</sup>H]-glycine was added to each well and the incubation was continued for 15 minutes. The cells were washed twice in HBS. Scintillation fluid was added and the Plates were counted on a Trilux (Wallac) scintillation counter.

The test results showed, that the prepared compounds of the invention all showed inhibition below 10000 nM as IC<sub>50</sub> in the above-mentioned assay.

The compounds of the invention were also tested in a well-recognised and reliable microdialysis test.

### Method

- 5 Male Sprague-Dawley rats, initially weighing 275 - 350 g, were used. The animals were housed under a 12-hr light/dark cycle under controlled conditions for regular indoor temperature ( $21\pm 2^{\circ}\text{C}$ ) and humidity ( $55\pm 5\%$ ) with food and tap water available *ad libitum*.
- 10 Rats were anaesthetized with hypnorm/dormicum (2ml/kg) and intracerebral guide cannulas (CMA/12) were stereotactically implanted into the brain positioning the dialysis probe tip in the ventral hippocampus (co-ordinates 5.6 mm posterior to bregma, lateral -5.0 mm, 7.0 mm ventral to dura). The rats were allowed to recover from surgery for at least 2 days. On the day of the experiment, a microdialysis probe
- 15 (CMA/12, 0.5 mm diameter, 3 mm length) was inserted through the guide cannula. The probes were connected via a dual channel swivel to a microinjection pump. Perfusion of the microdialysis probe with filtered Ringer solution (145 mM NaCl, 3 mM KCl, 1 mM  $\text{MgCl}_2$ , 1.2 mM  $\text{CaCl}_2$ ) was begun shortly before insertion of the probe into the brain and continued for the duration of the experiment at a constant
- 20 flow of 1  $\mu\text{l}/\text{min}$ . After 165 min of stabilization, the experiments were initiated. A 20 or 40 min sampling regime was used throughout the experimental period. Time points were corrected for lag time of the perfusate from the microdialysis site to the probe outlet.
- 25 After the experiments, the rats were sacrificed by decapitation. The brains were removed, frozen and sectioned (20  $\mu\text{m}$ ), and the position of the probes was verified.

### Analysis of glycine in the dialysates

- The concentration of glycine in the dialysates was analyzed by means of HPLC with
- 30 fluorescence detection after precolumn online derivatisation with o-phthalaldehyde. The system consisted of a Hypersil AA-ODS column (5  $\mu\text{m}$ , 2.1 x 200 mm, Agilent) with a Agilent 1100 fluorescence detector (excitation, 266-340 nm; emission, 305-340 nm). Mobile phases consisted of A: 20 mM sodium acetate, 0.018% triethylamine, 0.3

% tetrahydrofuran, pH 7.2. B: 20 mM sodium acetate, 40% acetonitrile and 40% methanol, pH 7.2. The oven temperature was set at 40°C and flow rate was 0.45 ml/min. Data were collected and analysed using ChemStation software (Agilent) after calibration with a range of standard glycine solutions (0.1 –10  $\mu$ M).

### **Data presentation**

The mean value of 3 consecutive glycine samples immediately preceding compound administration served as the basal level for each experiment and data were converted to percentage of basal (mean basal pre-injection values normalized to 100%).
